C++ Classes & Object Oriented Programming

Object Oriented Programming

 Programmer thinks about and defines the attributes and behavior of objects.

 Often the objects are modeled after realworld entities.

 Very different approach than function-based programming (like C).

Object Oriented Programming

- Object-oriented programming (OOP)
 - Encapsulates data (attributes) and functions (behavior) into packages called classes.
- So, Classes are user-defined (programmerdefined) types.
 - Data (data members)
 - Functions (member functions or methods)
- In other words, they are structures + functions

- A class definition begins with the keyword class.
- The body of the class is contained within a set of braces, { }; (notice the semi-colon).

- Within the body, the keywords private: and public: specify the access level of the members of the class.
 - the default is private.
- Usually, the data members of a class are declared in the *private*: section of the class and the member functions are in *public*: section.

- Member access specifiers
 - public:
 - can be accessed outside the class directly.
 - The public stuff is *the interface*.
 - private:
 - Accessible only to member functions of class
 - Private members and methods are for internal use only.

Class Example

 This class example shows how we can encapsulate (gather) a circle information into one package (unit or class)

```
class Circle
{
    private:
        double radius;
    public:
        void setRadius(double r);
        double getDiameter();
        double getArea();
        double getCircumference();
};
```

No need for others classes to access and retrieve its value directly. The class methods are responsible for that only.

They are accessible from outside the class, and they can access the member (radius)

Creating an object of a Class

- Declaring a variable of a class type creates an object.
 You can have many variables of the same type (class).
 - Instantiation
- Once an object of a certain class is instantiated, a new memory location is created for it to store its data members and code
- You can instantiate many objects from a class type.
 - Ex) Circle c; Circle *c;

Special Member Functions

Constructor:

- Public function member
- called when a new object is created (instantiated).
- Initialize data members.
- Same name as class
- No return type
- Several constructors
 - Function overloading

Special Member Functions

```
class Circle
                                                  Constructor with no
                                                  argument
   private:
         double radius;
                                                  Constructor with one
   public:
                                                  argument
         Circle();
         Circle(int r);
         void setRadius(double r);
         double getDiameter();
         double getArea();
         double getCircumference();
```

Implementing class methods

- Class implementation: writing the code of class methods.
- There are two ways:
 - 1. Member functions defined outside class
 - Using Binary scope resolution operator (::)
 - "Ties" member name to class name
 - Uniquely identify functions of particular class
 - Different classes can have member functions with same name
 - Format for defining member functions

```
ReturnType ClassName::MemberFunctionName() {
    ...
}
```

Implementing class methods

- 2. Member functions defined inside class
 - Do not need scope resolution operator, class name;

```
class Circle
{
    private:
        double radius;
    public:
        Circle() { radius = 0.0;}
        Circle(int r);
        void setRadius(double r){radius = r;}
        double getDiameter(){ return radius *2;}
        double getArea();
        double getCircumference();
};
```

```
class Circle
   private:
         double radius;
   public:
         Circle() { radius = 0.0;}
         Circle(int r);
         void setRadius(double r){radius = r;}
         double getDiameter(){ return radius *2;}
         double getArea();
         double getCircumference();
};
Circle::Circle(int r)
   radius = r;
double Circle::getArea()
   return radius * radius * (22.0/7);
double Circle:: getCircumference()
   return 2 * radius * (22.0/7);
```

Defined outside class

Accessing Class Members

- Operators to access class members
 - Identical to those for structs
 - Dot member selection operator (.)
 - Object
 - Reference to object
 - Arrow member selection operator (->)
 - Pointers

```
class Circle
   private:
        double radius;
   public:
                                                            The second
        Circle() { radius = 0.0;}
        Circle(int r);
                                                            constructor is
        void setRadius(double r){radius = r;}
                                                               called
        double getDiameter(){ return radius *2;}
        double getArea();
                                                                 Since radius is a
                                    void main()
        double getCircumference();
                                                                 private class data
                                         Circle c1, c2(7);
                                                                     member
Circle::Circle(int r)
                                         cout<<"The area of &
  radius = r;
                                              <<cl.getArea // \n";
                                         //c1.raduis = 5;//syntax error
double Circle::getArea()
                                         c1.setRadius(5);
   return radius * radius * (22.0/7);
                                         cout<<"The circumference of c1:"</pre>
                                              << c1.getCircumference()<<"\n";
double Circle:: getCircumference()
                                         cout<<"The Diameter of c2:"
   return 2 * radius * (22.0/7);
                                              <<c2.getDiameter()<<"\n";
```

```
class Circle
   private:
         double radius;
   public:
         Circle() { radius = 0.0;}
         Circle(int r);
         void setRadius(double r){radius = r;}
         double getDiameter(){ return radius *2;}
         double getArea();
         double getCircumference();
                                      void main()
Circle::Circle(int r)
                                           Circle c(7);
   radius = r;
                                           Circle *cp1 = &c;
                                           Circle *cp2 = new Circle(7);
double Circle::getArea()
                                           cout << "The are of cp2:"
  return radius * radius * (22.0/7);
                                                        <<cp2->getArea();
double Circle:: getCircumference()
   return 2 * radius * (22.0/7);
```

Destructors

- Destructors
 - Special member function
 - Same name as class
 - Preceded with tilde (~)
 - No arguments
 - No return value
 - Cannot be overloaded
 - Before system reclaims object's memory
 - Reuse memory for new objects
 - Mainly used to de-allocate dynamic memory locations

Another class Example

This class shows how to handle time parts.

```
class Time
   private:
       int *hour, *minute, *second;
    public:
       Time();
       Time(int h,int m,int s);
       void printTime();
       void setTime(int h,int m,int s);
       int getHour() {return *hour;}
       int getMinute() {return *minute;}
       int getSecond() {return *second;}
       void setHour(int h) {*hour = h;}
       void setMinute(int m) {*minute = m;}
       void setSecond(int s) {*second = s;}
       ~Time();
```

Destructor

Dynamic locations should be allocated to pointers first

```
Time::Time()
       hour = new int;
       minute = new int;
       second = new int;
       *hour = *minute = *second = 0;
Time::Time(int h,int m,int s)
       hour = new int;
       minute = new int;
       second = new int;
       *hour = h;
       *minute = m;
       *second = s;
void Time::setTime(int h,int m,int s)
       *hour = h;
       *minute = m;
       *second = s;
```

```
void Time::printTime()
     cout<<"The time is : ("<<*hour<<":"<<*minute<<":"<<*second<<")"</pre>
                >>endl;
                                       Destructor: used here to de-
                                        allocate memory locations
Time::~Time()
        delete hour; delete minute; delete second;
void main()
        Time *t;
        t = new Time(3, 55, 54);
        t->printTime();
        t->setHour(7);
        t->setMinute(17);
        t->setSecond(43);
                                        When executed, the
        t->printTime();
                                         destructor is called
        delete t;
```

Reasons for OOP

- 1. Simplify programming
- 2. Interfaces
 - Information hiding:
 - Implementation details hidden within classes themselves
- 3. Software reuse
 - Class objects included as members of other classes
